## 1. General information

All chemicals were used as received, unless otherwise noted. All reported NMR spectra were recorded on a 500 MHz spectrometer unless otherwise noted. Chemical shifts ( $\delta ; \mathrm{ppm}$ ) for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR were determined with TMS as the internal reference. $J$ values are given in Hz . Absorption and fluorescence spectra were recorded in cyclohexane, toluene, tetrahydrofuran, dichloromethane and acetonitrile. Mass spectra were obtained with an El ion source and EBE double focusing geometry mass analyzer or from a spectrometer equipped with an electro-spray ion source with Q-TOF type mass analyzer.

## Two-photon absorption spectral measurements.

Two-photon absorption (TPA) spectra were measured by the open-aperture Z-scan method ${ }^{1}$ with a femtosecond optical parametric amplifier (Spectra-Physics TOPAS Prime) as the wavelength-tunable light source. The setup for the measurements and the analysis are only described briefly here, because they have been previously reported in detail. ${ }^{2}$ In the Z-scan measurements, transmittance is recorded as function of sample position, scanned along the beam propagation direction of the focused laser beam. Typical examples of the open-aperture Z-scan traces are shown in Figs. S1-3 as examples. The transmittance is normalized to that at a sample position far from the focal point and is theoretically described as,

$$
\begin{equation*}
T(\zeta)=T_{N} \frac{1}{\sqrt{\pi} q(\zeta)} \int_{-\infty}^{+\infty} \ln \left[1+q(\zeta) e^{-x^{2}}\right] d x \tag{S1}
\end{equation*}
$$

for a two-photon absorber excited by spatially and temporally Gaussian pulses. Here, $T_{N}=$ $\exp (-\alpha L)$ is the linear transmittance of the sample, $\alpha$ is the linear absorption coefficient, $L$ is the physical path length of the sample, and $\zeta$ is the normalized sample position $\zeta=z / z_{R}$ with the Rayleigh length $z_{R} . q(\zeta)$ is the on-axis two-photon absorbance $q(\zeta)=q_{0} /\left(1+\zeta^{2}\right)$ with the on-axis two-photon absorbance at the sample position $q(0)=q_{0}$. This $q_{0}$ is related to the twophoton absorption coefficient $\beta$ by,

$$
\begin{equation*}
q_{0}=\beta I_{0} L \tag{S2}
\end{equation*}
$$

where $I_{0}$ is the on-axis peak intensity of the incident pulse. For the measurements performed using a fixed incident power (i.e., a fixed $I_{0}$ ), $\beta$ was calculated by assuming the proportionality relation of eq. S2. Practically, artifacts or unwanted processes may cause apparent deviation from proportionality, so we also recorded the incident-power dependence (i.e., by changing $I_{0}$ )
at some wavelengths to check this relationship. In this case, $\beta$ was determined from the slope of the plot of $q_{0}$ against $I_{0}$. The data points obtained by this method were shown with error bars in Fig. 2 in the main text. Finally, the TPA cross section $\sigma^{(2)}$ was obtained from $\beta$ by using the convention $\sigma^{(2)}=h v \beta / N$, where $h v$ is the photon energy of the excitation pulse and $N$ is the number density of the sample molecule calculated from the concentration.

The dyes were dissolved in spectroscopic grade dichloromethane (Fuji Film-Wako). Solutions were then held in 2-mm cuvettes whose path length is short enough against $z_{R}$ ( $7-10 \mathrm{~mm}$ ) to satisfy the thin sample condition for eq. S1. To avoid unwanted effects such as interference by photoproducts etc., the samples were stirred by a micro rotor put in the cell during the measurements. No significant degradation was observed for the samples after Z-scan measurements, which is confirmed by UV-vis measurements. For calibration of day-by-day fluctuation of the measured values, inhouse standard materials were measured at the same time with the samples (MPPBT in dimethyl sulfoxide ${ }^{3,4}$ ).

The open aperture z-scan traces at 650 nm or shorter for $\mathbf{7}$ showed saturable absorption (SA) as shown in Fig. S4. These z-scan traces were analyzed by phenomenological modeling of SA as

$$
\begin{equation*}
\alpha=\alpha(I(\zeta))=\frac{\alpha_{0}}{\left(1+I(\zeta) / I_{s}\right)} \tag{S3}
\end{equation*}
$$

where $I_{S}$ is saturation intensity and $I(\zeta)=I_{0} /\left(1+\zeta^{2}\right) .{ }^{5}$

## Quantum chemical calculations.

Molecular structures were optimized at the CAM-B3LYP/6-31+G(d) level of theory. The appropriateness of the obtained structures were checked by the absence of negative frequency in frequency calculations. The optimized structures are shown in Fig. S9. Transition dipole moments and transition energies, and permanent dipole moments were calculated for the lowest 20 excited states using the Tamm-Dancoff Approximation (TDA) ${ }^{6}$ with the same level of theory (CAM-B3LYP/6-31+G(d)). All calculations were performed in the Gaussian program suit. ${ }^{7}$ Solvent effects were considered by the polarizable continuum model (PCM) for dichloromethane for all calculations In this model, the bulk effect induced by a reaction field is considered. The solvent is modeled as a continuous medium with a dielectric constant, and the solute molecule is placed inside a cavity in the media. The reaction field is formed by polarization of the solvent medium surrounding the cavity, so it is also applied to the solute molecule in the cavity, in addition to the external field of incident light. The shape of the cavity is overlapping
spheres in PCM in contrast to the single sphere in the Onsager model. ${ }^{8}$ Calculated features of the lowest 10 excited states of 6-8 are listed in Tables S1-S3, respectively.

For postprocessing of the TPA spectrum simulation, we used a homemade program on Igor Pro (Wavemetrics Inc.) based on reported procedures. ${ }^{9}$ The spectral simulation by this method gives relatively good agreement of the calculated TPA cross section for the molecules with short $\pi$ conjugation (containing a few double bonds) but overestimates for longer $\pi$-conjugation by one order of magnitude of more. A rigorous explanation of the overestimation is not easy, but it often originates from the overestimation of transition dipole moments. The overestimation was enhanced for the higher-order (multiphoton) absorption process because the fourth power of transition dipole moments is necessary for TPA while only the square is needed for linear optical properties (OPA). The relaxation constants of OPA and TPA were set to 0.07 eV so that the OPA peak in the simulated spectrum matched to the 0-0 peak of the experimental one. The choice of the relaxation constants also directly affects the magnitude of the calculated TPA cross section because the height of the peak is inversely proportional to the square of the relaxation constant. Therefore, the comparison in absolute value to experiential results is very difficult. We would like to emphasize that the simulation results are useful for comparison of the relative shape of the spectra and clarifying the nature of the transition (allowed/forbidden).

## 2. Synthesis

## Synthesis of 1,4-bis(4-methylphenyl)-2,5-bis(thiazol-2-yl)-1,4-dihydropyrrolo[3,2-b]pyrrole

 (4)Glacial acetic acid ( 7.5 mL ), toluene ( 7.5 mL ), 2-thiazolecarboxaldehyde ( $1,880 \mu \mathrm{~L}, 10 \mathrm{mmol}$ ) and $p$-toluidine ( $2,1.07 \mathrm{~g}, 10 \mathrm{mmol}$ ) were placed in a 50 mL round-bottom flask equipped with a magnetic stir bar. The mixture was stirred at $90^{\circ} \mathrm{C}$ in an oil bath for 30 min . After that time, $\mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{3} \cdot \mathrm{xH}_{2} \mathrm{O}(166 \mathrm{mg}$, ca. 0.5 mmol$)$ was added, followed by diacetyl ( $3,440 \mu \mathrm{~L}, 5 \mathrm{mmol}$ ). The resulting mixture was stirred at $90^{\circ} \mathrm{C}$ for another 3 h and then cooled to room temperature. The solvents were evaporated off and the residue dissolved in hot ACN. After naturally cooling to room temperature it was left overnight in a refrigerator. The resulting precipitate was filtered off, washed with cold ACN and dried under high vacuum.

Yellow solid. Yield: 780 mg (34\%). Spectroscopic properties were in agreement with the literature data. ${ }^{10}$

## Synthesis of 2,5-bis(formyl)-1,4-bis(4-methylphenyl)-1,4-dihydropyrrolo[3,2-b]pyrrole (5)

Alkylation: Compound 4 ( $1560 \mathrm{mg}, 3.4 \mathrm{mmol}$ ) was placed in round-bottom pressure flask equipped with magnetic stir bar. The solid was suspended in 57 mL of dry DMF under an inert atmosphere, followed by addition of methyl triflate ( $1.6 \mathrm{~mL}, 7 \mathrm{mmol}$ ). The resulting mixture was stirred at $130^{\circ} \mathrm{C}$ in an oil bath for 24 h . The solvent was evaporated off and the resulting oil was dissolved in hot DCM. After naturally cooling to room temperature it was left overnight in a refrigerator. The resulting precipitate was filtered off and washed with cold DCM. After drying under high vacuum, this material was used in the next step without any further purification.

Reduction and cleavage: Alkylated TAPP ( $1085 \mathrm{mg}, 1.4 \mathrm{mmol}$ ) was dissolved in 30 mL of MeOH and 50 mL of THF. $\mathrm{NaBH}_{4}(535 \mathrm{mg}, 14 \mathrm{mmol})$ was added in a few portions and the reaction mixture was stirred for 30 min at room temperature. Subsequently, 2 mL of acetone was added and the solvents evaporated under reduced pressure. The residue was extracted with DCM and brine. The combined organic layers were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and evaporated. The residue was dissolved in an ACN/THF mixture ( $150 \mathrm{~mL} / 50 \mathrm{~mL}$ ) and 30 mL of $0.05 \mathrm{M}(\mathrm{pH}=7)$ phosphate buffer was poured into this mixture. Then, $\mathrm{AgNO}_{3}(480 \mathrm{mg}, 2.8 \mathrm{mmol})$ in 20 mL of water was added. After 30 min , another identical solution of $\mathrm{AgNO}_{3}$ was added. After $24 \mathrm{~h}, 1.2 \mathrm{~mL}$ of $\mathrm{Et}_{3} \mathrm{~N}$ was added, and after another 30 min brine was added. The reaction mixture was filtered through a pad of Celite and the filtrate was extracted with DCM. The combined organic layers were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and evaporated. The residue was purified by column chromatography ( $\mathrm{SiO} \mathrm{O}_{2}, \mathrm{DCM}$ ).

Yellow solid. $200 \mathrm{mg}(41 \%) . \mathrm{mp} 208-209{ }^{\circ} \mathrm{C}^{1}{ }^{1} \mathrm{H} \mathrm{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 9.69$ (s, 2H), 7.36-7.31 $(\mathrm{m}, 8 \mathrm{H}), 6.89(\mathrm{~s}, 2 \mathrm{H}), 2.45(\mathrm{~s}, 6 \mathrm{H}) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 180.5,138.5,137.9,135.3$, 134.9, 130.0, 125.6, 101.4, 21.2 ppm. HRMS (EI) m/z: [M] ${ }^{+}$Calcd for $\mathrm{C}_{22} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{2} 342.1368$; Found 342.1375.

## Synthesis of compound 6

A dried Schlenk flask was charged with 5 ( $41 \mathrm{mg}, 120 \mu \mathrm{~mol}$ ) and an ACN/THF ( $3 \mathrm{~mL} / 1.5 \mathrm{~mL}$ ) mixture, followed by malononitrile ( $23 \mathrm{mg}, 350 \mu \mathrm{~mol}$ ). The reaction mixture was stirred at rt for 4 h . The resulting precipitate was filtered off and recrystallized from $\mathrm{CHCl}_{3} / \mathrm{MeOH}$.

Red solid. 53 mg (100\%). mp $270^{\circ} \mathrm{C}$ (decomp.). ${ }^{1} \mathrm{H} \mathrm{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 7.41$ (d, J=8.0 Hz, $4 \mathrm{H}), 7.39(\mathrm{~s}, 2 \mathrm{H}), 7.35(\mathrm{~s}, 2 \mathrm{H}), 7.22(\mathrm{~d}, J=8.0 \mathrm{~Hz}, 4 \mathrm{H}), 2.50 \mathrm{ppm}(\mathrm{s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ )
$\delta 144.5,140.1,137.8,136.3,132.3,131.1,126.8,114.5,113.7,97.8,76.1,21.2 \mathrm{ppm}$. HRMS (EI) $\mathrm{m} / \mathrm{z}$ : $[\mathrm{M}]^{+}$Calcd for $\mathrm{C}_{28} \mathrm{H}_{18} \mathrm{~N}_{6}$ 438.1593; Found 438.1592.

## Synthesis of compound 7

A dried Schlenk flask was charged with $5(200 \mathrm{mg}, 585 \mu \mathrm{~mol})$ and $\mathrm{K}_{2} \mathrm{CO}_{3}(323 \mathrm{mg}, 2.3 \mathrm{mmol})$. Dry THF ( 15 mL ) and dry $\mathrm{MeOH}(15 \mathrm{~mL})$ were then added. After three vacuum/argon cycles, dimethyl(1-diazo-2-oxopropyl)phosphonate ( $247 \mathrm{mg}, 1.3 \mathrm{mmol}$ ) was added and the reaction mixture was stirred at room temperature for 2 days. More dimethyl(1-diazo-2oxopropyl)phosphonate ( $247 \mathrm{mg}, 1.3 \mathrm{mmol}$ ) was added, and reaction mixture was stirred at room temperature for another 2 days. Further addition of dimethyl(1-diazo-2oxopropyl)phosphonate ( $247 \mathrm{mg}, 1.3 \mathrm{mmol}$ ) and stirring at room temperature for another 3 days led to complete conversion of starting material (attempts to accelerate the reaction by increasing the temperature resulted in the decomposition of the product). The solvents were evaporated off under reduced pressure. The residue was dissolved in DCM and extracted with saturated $\mathrm{NaHCO}_{3(a q)}$. The combined organic layers were extracted with brine, then dried over $\mathrm{MgSO}_{4}$ and evaporated. The resulting residue was dried under high vacuum and used in next step without any further purification.

A dried Schlenk flask was charged with Cul ( $6 \mathrm{mg}, 33 \mu \mathrm{~mol}$ ), $\mathrm{PdCl}_{2}\left(\mathrm{PPh}_{3}\right)_{2}(23 \mathrm{mg}, 33 \mu \mathrm{~mol})$ and 4-iodobenzonitrile ( $282 \mathrm{mg}, 1.23 \mathrm{mmol}$ ). The reagents were dissolved in a mixture of dry THF $(3.5 \mathrm{~mL})$ and dry $\mathrm{Et}_{3} \mathrm{~N}(1.7 \mathrm{~mL})$. A solution of crude 2,5-bis-(ethynyl)pyrrolopyrrole in 5 mL of dry THF was then added dropwise over the period of 1 h at room temperature and under argon. The reaction mixture was heated in an oil bath at reflux for 4 h . The mixture was cooled to room temperature and solvent evaporated off under reduced pressure. The residue was purified by column chromatography ( $\mathrm{SiO}_{2}, \mathrm{DCM} /$ hexanes, $1: 1$ ) and recrystallized from $\mathrm{CHCl}_{3} / \mathrm{MeOH}$.

Red solid. $53 \mathrm{mg}(17 \%) . \mathrm{mp} 290^{\circ} \mathrm{C}$ (decomp.). ${ }^{1} \mathrm{H} \mathrm{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 7.57$ (d, J = 8.0 Hz , $4 \mathrm{H}), 7.56(\mathrm{~d}, J=8.0 \mathrm{~Hz}, 4 \mathrm{H}), 7.39(\mathrm{~d}, J=8.0 \mathrm{~Hz}, 4 \mathrm{H}), 7.34(\mathrm{~d}, J=8.0 \mathrm{~Hz}, 4 \mathrm{H}), 6.63(\mathrm{~s}, 2 \mathrm{H}), 2.47 \mathrm{ppm}$ (s, 6H); ${ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 136.5,136.1,132.0,130.8,130.3,129.7,128.1,123.9,119.1$, 118.6, 110.1, 100.4, 94.4, 88.1, 21.1 ppm. HRMS (EI) m/z: [M] ${ }^{+}$Calcd for $\mathrm{C}_{38} \mathrm{H}_{24} \mathrm{~N}_{4}$ 536.2001; Found 536.2004.

## Synthesis of compound 8

Crude 2,5-bis-ethynylpyrrolopyrrole was prepared as described for 7.

A dried Schlenk flask was charged with 4-bromobenzaldehyde ( $238 \mathrm{mg}, 1.3 \mathrm{mmol}$ ), $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ ( 400 $\mathrm{mg}, 1.2 \mathrm{mmol}), \mathrm{Pd}(\mathrm{OAc})_{2}(33 \mathrm{mg}, 146 \mu \mathrm{~mol})$ and $\mathrm{PPh}_{3}(153 \mathrm{mg}, 585 \mu \mathrm{~mol})$. A solution of crude 2,5-bis-(ethynyl)pyrrolopyrrole in 8 mL of dry DMSO was then added. The mixture was degassed and refilled with argon 3 times. The reaction mixture was stirred at $80^{\circ} \mathrm{C}$ in an oil bath for 24 h after which it was cooled to room temperature and the solvent evaporated under reduced pressure. The residue was purified by column chromatography ( $\mathrm{SiO}_{2}, \mathrm{DCM} /$ hexanes $)$ and recrystallized from $\mathrm{CHCl}_{3} / \mathrm{MeOH}$.

Red solid. $13 \mathrm{mg}(4 \%) . \mathrm{mp} 257{ }^{\circ} \mathrm{C}$ (decomp.). ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 9.97$ (s, 2H), 7.81 (d, J $=8.2 \mathrm{~Hz}, 4 \mathrm{H}), 7.59(\mathrm{~d}, J=8.2 \mathrm{~Hz}, 4 \mathrm{H}), 7.47(\mathrm{~d}, J=8.2 \mathrm{~Hz}, 4 \mathrm{H}), 7.34(\mathrm{~d}, J=8.2 \mathrm{~Hz}, 4 \mathrm{H}), 6.64(\mathrm{~s}, 2 \mathrm{H})$, $2.47 \mathrm{ppm}(\mathrm{s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (126 MHz, $\mathrm{CDCl}_{3}$ ) $\delta 191.2,136.4,136.2,134.9,130.8,130.2,129.7$, 129.6, 129.5, 123.9, 119.2, 100.4, 95.2, 87.9, 21.1 ppm. HRMS (EI) m/z: [M] ${ }^{+}$Calcd for $\mathrm{C}_{38} \mathrm{H}_{26} \mathrm{~N}_{2} \mathrm{O}_{2}$ 542.1994; Found 542.2011.

## 3. Two-photon absorption studies

Figure S1. (left) Open-aperture Z-scan traces of $\mathbf{6}$ in dichloromethane ( 0.43 mM ) measured at 651 nm at different incident powers (symbols) with theoretical fits (grey curves). (right) The corresponding plot of the two-photon absorbance $q_{0}$ obtained from the curve fits with eq. S1 against the incident power in the left panel.

Figure S2. (left) Open-aperture Z-scan traces of 7 in dichloromethane ( 0.47 mM ) measured at 721 nm at different incident powers (symbols) with theoretical fits (grey curves). (right) The corresponding plot of the two-photon absorbance $q_{0}$ obtained from the curve fits with eq. S1 against the incident power in the left panel.

Figure S3. (left) Open-aperture Z-scan traces of $\mathbf{8}$ in dichloromethane $(0.70 \mathrm{mM})$ measured at 770 nm at different incident powers (symbols) with theoretical fits (grey curves). (right) The corresponding plot of the two-photon absorbance $q_{0}$ obtained from the curve fits with eq. S1 against the incident power in the left panel.

Figure S4. Open-aperture Z-scan trace of 7 (dots) in dichloromethane ( 0.52 mM ) measured at 583 nm (incident power of 0.4 mW ) with theoretical fits considering saturable absorption (grey curves) with eq. S3.

Table S4. Summary of the calculated parameters at the TDA-CAM-B3LYP $/ 6-31+G(d)$ level of theory for the first few TPA transitions. Transition path is $\mathrm{f} \leftarrow \mathrm{i} \leftarrow 0$, where destination state ( f ), intermediate state (i), and the ground state ( 0 ). Absolute values of transition dipole moments $\left(\left|\boldsymbol{\mu}_{\mathrm{f}}\right|\right.$ and $\left.\left|\boldsymbol{\mu}_{\mathrm{i} \mid}\right|\right)$, transition energies ( $E_{\mathrm{f}}$ and $E_{\mathrm{i}}$ ), detuning energy $\left(\Delta E_{\mathrm{det}}=E_{\mathrm{i}}-E_{\mathrm{f}} / 2\right)$, the angle $(\theta)$ between the transition dipole moments $\boldsymbol{\mu}_{\mathrm{fi}}$ and $\boldsymbol{\mu}_{\mathrm{i} 0}$. The three-state model was used to calculate the relative magnitude of the component of TPA cross section via the $\mathrm{f} \leftarrow \mathrm{i} \leftarrow 0$ path ( $\sigma_{\mathrm{TPA}, \mathrm{rel}}=F_{\mathrm{TDM}} F_{\text {det }} F_{\text {ang }}$ ), where TPA transition dipole moments factor ( $F_{\mathrm{TDM}}=$ $\left.\left|\boldsymbol{\mu}_{\mathrm{fi}}\right|^{2}\left|\boldsymbol{\mu}_{\mathrm{i} 0}\right|^{2}\right)$, detuning-energy factor $\left(F_{\mathrm{det}}=\left(\frac{E_{\mathrm{f}} / 2}{E_{\mathrm{i}}-E_{\mathrm{f}} / 2}\right)^{2}=\left[\Delta E_{\mathrm{det}} /\left(E_{\mathrm{f}} / 2\right)\right]^{-2}\right)$, angle factor $\left(F_{\mathrm{ang}}=1+2 \cos ^{2} \theta\right)$. See ref. S8 for the detailed definitions.

| cmpd | $\mathrm{f} \leftarrow \mathrm{i} \leftarrow 0$ | $\boldsymbol{\mu}_{\mathrm{fi}} \mid / \mathrm{D}$ | $\left\|\boldsymbol{\mu}_{\mathrm{i} 0}\right\| / \mathrm{D}$ | $E_{\mathrm{f}} / \mathrm{eV}$ | $E_{\mathrm{i}} / \mathrm{eV}$ | $\Delta E_{\text {det }} / \mathrm{eV}$ | $\theta /{ }^{\circ}$ | $F_{\text {TDM }} / \mathrm{D}^{4}$ | $F_{\text {det }}$ | $F_{\text {ang }}$ | $\sigma_{\text {TPA,rel }}$ |
